

ABSTRACT OF THE DISCLOSURE

A message processing scheme capable of realizing both a portability and a unified way of handling and managing e-mails of a given user is disclosed. The collective message processing and the unified message accesses are realized by storing and managing messages from a plurality of message delivery servers in the message processing device that is unique to the user. All mails destined to the user are collected at the message processing device regardless of a current location of the user, so that the user only needs to view mails on this message processing device.
